**(54) Mounting device for mounting electric and/or electronic parts**

(57) A mounting device for mounting electric and/or electronic parts of different sizes at a specific position comprising a head unit movable in horizontal and vertical directions to mount said parts preferably on a substrate such as a printed circuit board. The device further comprises an optical detecting means and an image pickup means for selectively detecting the state of parts of different sizes. The first detection position of the optical detecting means is different from a second detection position of the image pickup means.

**FIGURE 3**

**EP 0 725 560 A2**

## Description

This invention relates to a mounting device for mounting electric and/or electronic parts of different sizes at a specific position, preferably on a substrate such as a printed circuit board, comprising a head unit movable in horizontal and vertical directions, an optical detecting means and an image pickup means for selectively detecting the state of parts of different sizes.

A type of mounter has been known which picks up parts such as ICs by a head unit having a nozzle member for picking up the parts from a parts supply section, moves them over a positioned printed circuit board, and mount them in specified positions on the printed circuit board.

When this type of mounter is used, the position of the parts where they are picked up by the nozzle member has some extent of variation, and the mounting position has to be corrected according to the deviation. At the same time, the mounter is required to prevent defective parts such as those with broken leads from being mounted.

In order to detect such a state of the part, the picked up part is inspected for example by providing the head unit with optical detecting means having a parallel light emitting section and a light receiving section facing each other. According to this means, the picked up part is placed between the light emitting section and the light receiving section, namely in a detection area of the optical detecting means and then a parallel light beam is cast on the picked up part. From the projection (shadow) of the part, the state of the part is detected.

This type of mounter is required to mount various parts of different sizes, in most cases small sized chip parts. However, it is also required sometimes to mount large sized parts such as QFPs and connectors. In that case, to make it possible to detect such large sized parts using the optical detecting means, the distance between the light emitting section and the light receiving section as well as the lengths of such sections of the optical detecting means have to be increased according to the parts to be detected.

However, if the distance between the emitting section and the light receiving section and their lengths are increased, it becomes likely that effect of noise on the parallel light beam increases, and errors occur in the positioning of the light emitting section and the light receiving section. As a result, it is possible that detection accuracy for the part especially for small parts lowers. Therefore, the lowering in the detection accuracy has to be avoided.

Another problem is the increase in the size of the apparatus due to the increase in the distance between the light emitting section and the light receiving section, which has to be avoided too.

In addition to the optical detecting means for detecting parts, there is an image pickup means for detecting the part state according to picked up images. Selective use of the optical detecting means and the image

pickup means depending on the types of parts is proposed (Japanese patent application No. Hei 4-296124). However, even in that case, if detection of large sized parts is to be made, interference between the part and the optical detecting means has to be avoided. Therefore, in that case too, increase in the distance between the light emitting section and the light receiving section as well as their sizes causes the problem described above.

Accordingly, it is an objective of the present invention to provide an improved mounting device for mounting electric and/or electronic parts as indicated above which always ensures a reliable detection of the positions as well as the states of electric and/or electronic parts.

According to the invention, this objective is solved for a mounting device for mounting electric and/or electronic parts as indicated above in that a first detection position of the optical detecting means is different from a second detection position of the image pickup means.

The reliability is further enhanced by the mounting device comprising a main controller for controlling the selection of the optical detection means and the image pickup means. Thereby, it is advantageous when the main controller comprises a main operation section for controlling the optical detection means or the image pickup means, respectively.

According to a further embodiment, the optical detecting means of said mounting device comprises a laser beam generating section and light receiving section especially for small parts.

Thus, it is advantageous when the image pickup means for large parts comprises a first light emitting unit and pickup camera, whereby the reliability may be further enhanced by a second light emitting unit and that the first light emitting unit is usable for transmitted light detection, whereby the second light emitting unit is usable for impinging light detection.

Other preferred embodiments of the present invention are laid down in further dependent claims.

According to this invention, the optical detecting means and the image pickup means can be selectively used depending on the size of the part to be picked up. When the part is small and can be detected by projection using the optical detecting means, the part is picked up and brought to the first detection height by the movement of the nozzle member, a parallel light beam is cast from the light emitting section of the optical detecting means to the part, and the part state is detected according to the projection. When the part is large on the other hand, the image pickup means is selected for use. In that case, the part is picked up and brought to the second detection height by the movement of the nozzle member, the picked up part is brought to a specified image pickup position by the movement of the head unit and in that state the part image is picked up by the image pickup means, and the part state is detected from the image recognition. Here, the "part state" means

defects and positional deviation of the part picked up by the nozzle member.

In the following, the present invention is explained in greater detail with respect to several embodiments thereof in conjunction with accompanying drawings, wherein:

FIG. 1 is a plan view of a mounter to which an example of the part state detecting device of this invention is applied;

FIG. 2 is a front elevation of the above mounter;

FIG. 3 is an enlarged oblique view of an essential portion of the part state detecting device of this invention;

FIG. 4 is a block diagram showing an example of the control system of the mounter; and

FIG. 5 is a flow chart showing the control for the part state detection.

FIGs. 1 and 2 show a structure of a mounter provided with a part state detecting device according to a first embodiment. As shown in the drawings, a conveyor 2 for conveying printed circuit boards is arranged on a base 1 of the mounter so that the printed circuit board 3 is conveyed on the conveyor 2 and stopped at a specified mounting work position. On both sides of the conveyor 2 are arranged part supply sections 4 provided with feeders, for example multiple rows of tape feeders 4a, for supplying the parts.

A head unit 5 for mounting parts is provided above the base 1. The head unit 5 is made to be capable of moving between the parts supply section 4 and the parts mounting section where the printed circuit board 3 is placed. In this embodiment, the movement is possible in directions of X axis (the direction of the conveyor 2) and Y axis (the direction normal to the X axis in a horizontal plane).

On the base 1 are arranged stationary rails 7 in the direction of Y axis, and a ball screw shaft 8 driven for rotation by a Y axis servomotor 9. A head unit support member 11 is arranged on the stationary rails 7. A nut 12 provided on the support member 11 engages with the ball screw shaft 8. An X direction guide member 13 and a ball screw shaft 14 driven by an X axis servomotor 15 are arranged on the support member 11. The head unit 5 is movably supported by the guide member 13. A nut (not shown) provided on the head unit 5 engages with the ball screw shaft 14. The support member 11 is moved by the Y axis servomotor 9 in the Y axis direction. The head unit 5 is moved by the X axis servomotor 15 in the X axis direction relative to the support member 11.

The Y axis servomotor 9 and the X axis servomotor 15 are provided with position detecting devices 10 and 16, each comprising a rotary encoder so as to detect moved positions of the head unit 5.

The head unit 5 is provided with a nozzle member 21 for picking up the part. The nozzle member 21 is made capable of moving in vertical Z axis direction and

in rotary direction about the nozzle center R axis as driven by a Z axis servomotor 17 and an R axis servomotor 19. These servomotors 17 and 19 are provided with position detecting devices 18 and 20 respectively to detect moved positions of the nozzle member 21.

Though not shown, the nozzle member 21 is connected to a negative pressure applying means through a valve or the like so that a negative pressure is applied, when needed for picking up the part, to the nozzle tip.

The head unit 5 is also provided at its lower end portion with a laser unit 22 as optical detecting means for detecting the state of the picked up part, e.g. defects and positional deviation of the picked up part relative to the nozzle member 21. As shown in FIG. 3, the laser unit 22 comprises laser beam generating section (parallel light beam emitting section) 22a and a detector (light receiving section) 22b facing each other on both sides of a space through which the nozzle member 21 passes when it moves up and down.

The head unit 5 is further provided, on the undersides of the laser beam generating section 22a and the detector 22b of the laser unit 22, with light emitting units 23a and 23b respectively, and, at a position above the laser unit 22 and corresponding to a space between the laser beam generating section 22a and the detector 22b, with a light emitting unit 23c. The light emitting unit 23c is attached to a frame of the head unit 5 and, as shown in FIG. 3, a through hole 24 is bored in its center so that the nozzle member 21 passes the light emitting unit 23c through the hole 24.

These light emitting units 23a, 23b, and 23c; hereinafter collectively referred to as the first light emitting unit 23 emit light, when an image of the part is to be picked up by a part recognizing or pickup camera 25 which will be described later, from behind (topside) the part picked up by the nozzle member 21.

Beside the part supply section 4 is arranged the part recognizing camera 25 as means for picking up the image of the part picked up by the nozzle member 21 and above it is arranged a second light emitting unit 26 for casting light beam on the head side (underside) of the part picked up by the nozzle member 21.

The part recognizing camera 25 is a CCD camera for example constituted to pick up the image of the part in two dimensions through an image pickup opening 26a formed in the second light emitting unit 26.

When the image of the part is to be picked up by the part recognizing camera 25, either the first or second light emitting unit 23 or 26 emits light depending on the type of the part from which the image is to be picked up. This arrangement is such that, when the first light emitting unit 23 emits light, an image obtained when the light transmits the part (transmission image) is picked up and when the second light emitting unit 26 emits light, an image obtained when the light is reflected from the part surface (reflection image) is picked up.

Next, a control system of the mounter will be described in reference to FIG. 4 which shows a block

diagram showing an example of the control system of the mounter.

In FIG. 4, servomotors 9, 15, 17, and 19 respectively of the Y axis, X axis, Z axis for the nozzle member 21 of the head unit 5, and R axis, and position detection means 10, 16, 18, and 20 provided respectively on those servomotors are electrically connected to the shaft controller 31. The laser unit 22 is electrically connected to a laser unit operation section 35. The laser unit operation section 35 is connected through the input-output means 32 of the main controller 30 to the main operation section 33. Light emitting units 23 and 26 are connected to the input-output means 32.

The part recognizing camera 25 is connected to an image processing section 34 of the main controller 30. In the image processing section 34, the part image picked up is subjected to predetermined image processing for the recognition of the part picked up so that the state of the part such as defects and deviation in the picked up position of the part is detected.

The main operation section 33 controls the movements of the servomotors 9, 15, 17, and 19 through the shaft controller 31 according to mounting data stored in a memory section (not shown) or the data concerning parts to be mounted, mounting positions, mounting order, etc. and also selects the laser unit 22 or the part recognizing camera 25 to be used for the part state detection according to the type of the part to be processed, and controls according to that selection.

In other words, it is arranged as follows: When the part state can be detected by the laser unit 22, namely if the part is smaller than a predetermined size which can be placed and rotated in the space (detection area of the laser unit 22) between the laser beam generating section 22a and the detector 22b of the laser unit 22 and if the shape is relatively simple for example, the laser unit 22 is selected. When the part state is difficult or impossible to detect by the laser unit 22, for example because the part has many leads or such a large size that interferes with laser beam generating section 22a and the detector 22b when the part is placed and rotated in the scanning area of the laser unit 22, the part recognizing camera 25 is selected. Control is made according to such a selection. When the part recognizing camera 25 is selected, selection is further made whether a reflection image or a transmission image should be picked up and the first light emitting unit 23 or the second light emitting unit 26 is selected to emit light accordingly.

The part state detecting action of the mounter constituted as described above will be described in reference to the flow chart in FIG. 5.

When the mounting action is started in the mounter, first in the step S1, Y axis servomotor 9 and the X axis servomotor 15 are driven to move the head unit 5 to the part pickup position. Then the Z axis servomotor 17 is driven to lower the nozzle unit 21 (steps S1, and S2). Thus, the part is picked up by the nozzle member 21 (step S3).

Next, whether the laser unit 22 or the part recognizing camera 25 should be used to detect the part state is determined. In other words, previously stored data of the part is read and, if the size of the part is not larger than a predetermined value which can be projected and detected by the laser unit 22, the laser unit 22 is selected and, if the part size is larger than that value, the part recognizing camera 25 is selected. When the part recognizing camera 25 is selected, the process moves on to the step S5 and, when the laser unit 22 is selected, the process moves on to the step S11 (step S4).

When the part recognizing camera 25 is selected in the step S4, the nozzle member is raised so that the picked up part is located in a detection position slightly below the laser unit 22 (position  $Z_2$  or the second detection height) and the head unit 5 is moved to a position above the part recognizing camera 25 (steps S5 and S6).

Then either of the light emitting units 23 or 26 is selected to emit light (step S7). Under that state, the image of the part is picked up by the part recognizing camera 25 (step S8). In the step S9, the part is recognized by the image processing section 34. At the same time, defects and deviation in the picked up position of the part are detected according to the part recognition and, if necessary, the amount of correction at the time of mounting is determined. As an example of such a process, image of the part is scanned in the image processing section 34, the part center and the part rotation angle about the R axis are determined from the scanning, and correction amounts in the X, Y, and rotary directions are determined from the positional deviation of the part center and rotary angle deviation relative to the part pickup point as picked up by the pickup nozzle.

In the next step S10, the part is mounted: When the head unit 5 moves over the printed circuit board 3 and reaches the corrected mounting position, the nozzle member 21 lowers and the part is mounted on the printed circuit board 3. Thus, the process shown in the flow chart is finished.

When the laser unit 22 is selected in the step S4 on the other hand, the nozzle member is raised so that the picked up part is located to a specified position within the detection area of the laser unit 22 (position  $Z_1$  in FIG. 3 or the first detection height), the part state is detected by the laser unit 22, and the correction amount at the time of mounting is determined (steps S11 - S13). As a process to determine such a correction amount, for example, the part picked up by the nozzle member 21 is held at a height  $Z_1$  corresponding to the laser unit 22 and rotated. A laser beam is cast from the laser beam generating section 22a on the part and the projection width of the part is detected by the detector 22b receiving the laser beam. Correction amounts in the X, Y, and rotary directions are determined from the projection width, center position, and rotary angle, at a point where the projection width becomes the minimum.

When such a processing is over, the step moves on to the step S10 in which the part is mounted to finish the process shown in the flow chart.

As described above, when such a mounter is used, since the part state such as defects and deviation in the part pickup position are detected by the selective use of the laser unit 22 and the part recognizing camera 25, when the laser unit 22 is used, the distance between the laser beam generating section 22a and the detector 22b is set within the range capable of sufficiently securing the detection accuracy, and thereby the accuracy of detection of the laser unit 22 is secured. On the other hand, when it is impossible to place the part within the detection area between the laser beam generating section 22a and the detector 22b, the part can be detected by the part recognizing camera 25. As a result, the part state can be accurately detected for all the picked up parts. In particular, when the image of the part is picked up by the part recognizing camera 25, the nozzle member 21 is controlled so that the picked up part is positioned (at a position  $Z_2$ ) below the laser unit 22. Therefore, the laser unit 22 is reliably prevented from interfering with the picked up part.

The problem of increased size associated with the conventional device caused by the increase in the distance between the laser beam generating section 22a and the detector 22b is also avoided.

When the part image is picked up by the part recognizing camera 25, either transmission image or reflection image can be selectively picked up by selectively emitting light from either the first light emitting unit 23 or the second light emitting unit 26. This is an advantage of increased degree of freedom in picking up the image.

The mounter described above is an embodiment to which an example of the part recognizing device according to this invention is applied. The specific structure can be modified as long as it does not depart from the spirit of this invention. For example, while the above embodiment employs the part recognizing camera 25 consisting of a CCD camera as image pickup means for picking up images in two dimensions, image pickup means consisting of line sensors may also be employed. In that case, since the part image is picked up while the part is being moved relative to the line sensors, mounting efficiency can be increased in comparison with the part recognizing camera 25 requiring stop of the part at a specified image pickup position.

While the above embodiment employs one nozzle member for picking up and mounting the part, plural number of nozzle members may be employed to increase mounting efficiency.

According to the part state detecting device of this invention described above, the optical detection means and the image pickup means are provided. The part state is detected by either of the means depending on the types of the parts. When the part is small and can be detected by projection using the optical detection means, the optical detection means is selected, the picked up part is placed at the first detection height

within the detection area of the optical detection means, and the part state is detected from the part projection. When the part is large, the picked up part is placed at the second detection height, and the part is recognized on the basis of the picked up image. As a result, the part state can be detected accurately according to the types of the parts. Furthermore, since the optical detection means can be formed relatively small, detection mechanism and device can be made in a compact size.

## Claims

1. A mounting device for mounting electric and/or electronic parts of different sizes at a specific position, preferably on a substrate such as a printed circuit board, comprising a head unit (5) movable in horizontal and vertical directions, an optical detecting means (22) and an image pickup means (23, 25, 26) for selectively detecting the state of parts of different sizes, **characterized in that** a first detection position ( $Z_1$ ) of the optical detecting means (22) is different from a second detection position ( $Z_2$ ) of the image pickup means (23, 25, 26).
2. A mounting device as claimed in claim 1, **characterized by** a main controller (30) for controlling the selection of the optical detecting means (22) and the image pickup means (23, 25, 26).
3. A mounting device as claimed in claim 2, **characterized in that** said main controller (30) comprises a main operation section (33) for controlling the optical detecting means (22) or the image pickup means (23, 25, 26), respectively.
4. A mounting device as claimed in claims 1-3, **characterized in that** the optical detecting means (22) comprises a laser beam generating section (22a) and a light receiving section (22b).
5. A mounting device as claimed in claims 1-4, **characterized in that** said image pickup means comprises a first light emitting unit (23) and a pickup camera (25).
6. A mounting device as claimed in claim 5, **characterized in that** a further, second light emitting unit (26) is provided and that the first light emitting unit (23) is usable for transmitted light detection, whereby the second light emitting unit (26) is usable for impinging light detection.
7. A mounting device as claimed in claim 5 or 6, **characterized in that** the first light emitting unit (23) comprises three light emitting units (23a, 23b, 23c).
8. A mounting device as claimed in claim 5 or 7, **characterized in that** the head unit (5) comprises a nozzle member (21) reciprocable along an axis (Z)

and that along this axis (Z) are arranged in turn one light emitting unit (23c) around said axis, the laser beam generating section (22a) and the light receiving section (22b) to both sides of the axis (Z), the second light emitting unit (26) around said axis (Z) and the pickup camera ((25) coaxially to said axis (Z).

9. A mounting device as claimed in claims 1-8, characterized in that the head unit (5) is connected to a negative pressure applying means.
10. A mounting device as claimed in claims 5-9, characterized in that the pickup camera (25) is a CCD camera.
11. A mounting device as claimed in claims 1-4, characterized in that the image pickup means (25) comprises line sensors.
